

Real time simulation: Continuum Robot Manipulator

Kinematics and actuation Methodology

- The most basic thing is to consider the simplest case: bending for a compliant beam structure.
- Curvature of the beam has the same value along the central axis of the robotic arm segment.
- the bent segment can be approximated as a segment of a string
- when the arm is bent with an angle of θ_x → the length of the inner tendon (2) is decreased with Δx even: $l_i = l - \Delta x$ and for the outer tendon (1) we can write also: $l_o = l + \Delta x$

↳ with the CC $\Rightarrow \begin{cases} l - \Delta x = r_1 \theta_x (*) \\ l + \Delta x = r_2 \theta_x (**) \end{cases} \rightarrow \theta_x = \frac{2\Delta x}{d} \quad (***)$

- Δx = displacement of the tendon pair
- d = distance b/w 2 antagonistic tendons
